Examples of good and poor terminal lug and compression quality

Aim

To demonstrate acceptable copper tube terminal lug crimping quality in terms of:

- Tube size and cross sectional area
- Material hardness
- Crimped joint characteristics

Method

A competitor's terminal lug designed to accept 95sqmm conductor was reviewed and compared with Cembre terminal lug ref. A19-M12.

Results

Terminal lug characteristics are summarised in Table 1.

Terminal lug ref.	I.D (mm)	Barrel cross sectional area	% of nom.	Hardness (Hv10)		Fully
rei.		(sqmm)	conductor CSA	Barrel	Palm	annealed
'95-14'	13.4	80.6	85	52.7	74.2	No
A19-M12	13.5	97.4	103	51.1	52.4	Yes

Table 1. Terminal lug comparison

- Barrel cross section of the competitor terminal lug is less than the cross sectional area of the conductor. This results in a lower current carrying capacity and potentially higher temperatures, generated during current flow.
- Palm hardness of competitor terminal lug is approximately 'half hard' indicating that products are not fully annealed after palm pressing. Residual stresses are still present within the palm area, which may lead to material fracture.
- A fully annealed terminal lug ensures better mechanical performance and improved electrical contact at the interface.

Page 2 of 6

Examples of poor quality crimped joints

Figure 1. Over-crimped condition

- Die set profile too small mismatched dies
- Excess flash generated as copper is extruded from the die area
- Electrical and mechanical performance compromised
- Crimp does not conform to BS 7609:1992

Figure 2. Under-crimped condition

- Die profile too large mismatched dies
- Insufficient deformation of terminal lug barrel to achieve effective filling ratio and compression
- Electrical and mechanical performance compromised

Page 3 of 6

Example of good quality crimped joint

Figure 3. Correctly crimped joint

- Correctly matched die set to terminal lug
- Correct filling ratio
- Best condition for conforming electrical and mechanical performance
